Abstract

16 The National Aeronautics and Space Administrations's (NASA) Hurricane and Severe Storm
17 Sentinel (HS3) investigation was a multi-year field campaign designed to improve understanding
18 of the physical processes that control hurricane formation and intensity change, specifically the
19 relative roles of environmental and inner-core processes. Funded as part of NASA's Earth
20 Venture program, HS3 conducted five-week campaigns during the hurricane seasons of 2012-14
21 using the NASA Global Hawk aircraft, along with a second Global Hawk in 2013 and a WB-57f
22 aircraft in 2014. Flying from a base at Wallops Island, Virginia, the Global Hawk could be on
23 station over storms for up to 18 hours off the East Coast of the U.S. to about 6 hours off the
24 western coast of Africa. Over the three years, HS3 flew 21 missions over 9 named storms, along
25 with flights over two non-developing systems and several Saharan Air Layer (SAL) outbreaks.
26 This article summarizes the HS3 experiment, the missions flown, and some preliminary findings
27 related to the rapid intensification and outflow structure of Hurricane Edouard (2014) and the
28 interaction of Hurricane Nadine (2012) with the SAL.

29

A multi-year field campaign to measure environmental and inner-core processes that lead to storm formation and intensification into major hurricanes.

30

31 Almost 60 million Americans live within counties along the East and Gulf Coasts (140
32 million total in East and Gulf coast states), thus exposing them to the potential destruction
33 caused by a landfalling hurricane. Societal vulnerability to damage has increased primarily
34 because of growth in both population and wealth in coastal zones from Texas to Maine. Pielke et
35 al. (2008) projected a doubling of economic losses from landfalling hurricanes every ten years.
36 Advances in airborne and satellite observing systems, computing technologies, numerical models,
37 and scientific understanding of hurricanes have led to significant advances in the understanding
38 of hurricane motion and subsequent improvements in track prediction. However, improvements
39 in prediction of storm intensity change have lagged due to an inadequate understanding of
40 the processes that cause it, insufficient sampling of appropriate observations of the storm
41 environment and internal processes, and inadequate representation of those processes in
42 models (Rogers et al. 2006).

43 For five weeks in each of the hurricane seasons of 2012-2014, the National Aeronautics and
44 Space Administration (NASA) conducted airborne campaigns using high-altitude long-duration
45 Unmanned Airborne Systems (UASs) to investigate the processes that underlie hurricane
46 formation and intensification. The Hurricane and Severe Storm Sentinel (HS3) mission, funded
47 under NASA's Earth Venture program, comprised a set of aircraft and payloads well suited for
48 the study of hurricanes and other severe weather systems. Using data from two Global Hawk
49 (GH) UASs, the HS3 goal was to better understand the physical processes that control intensity

50 change, specifically the relative roles of environmental and inner-core processes. This goal was
51 focused on the following science questions:

52

53 Environment:

54 1. What impact does the Saharan Air Layer (SAL) have on intensity change?

55 2. How do storms interact with shear produced by large-scale wind systems?

56 3. How does the outflow layer interact with the environment?

57

58 Inner core:

59 1. What is the role of deep convective towers (bursts) in intensity change? Are they
60 critical to intensification?

61 2. What changes in storm structure occur prior to and during genesis and rapid
62 intensification?

63 3. How do intrusions of dry air impact intensity change?

64

65 HS3 was designed to address these questions and to assess the impact, both in terms of
66 research and applications, of remote and in-situ data sets from the Global Hawks on modeling
67 and analysis. During its three deployments (Aug.-Sept. 2012, 2013, and 2014), HS3 obtained
68 observations over 9 named storms during 21 flights, along with additional flights over SAL
69 outbreaks and non-developing systems. HS3 demonstrated a key component of the observing
70 system envisioned by MacDonald (2005) by bringing to bear the high-altitude long-endurance
71 GH platform, a broad array of instruments, and new sampling strategies to provide data for in-
72 depth study, for assimilation into models, and for detailed evaluation and validation of models.

73

74 **AIRCRAFT**

75 HS3 utilized two of NASA’s unmanned GH aircraft [see Braun et al. (2013) for a
76 background on the aircraft] and selected distinct payload sets for each aircraft. One GH, known
77 as air vehicle one (AV-1) because it was the first GH ever built, was designated the “over-storm
78 GH” since it carried three instruments specifically designed to measure the inner-core structure
79 of storms. The second GH, known as AV-6, was designated the "environmental GH" because it
80 carried instruments designed to characterize the storm environment including temperature,
81 relative humidity, wind speed and direction, and profiles of Saharan dust. Unfortunately, due to
82 engine and electrical issues, AV-1 was unable to deploy to the field in 2012 and 2014. In 2014,
83 when it became clear that AV-1 would not deploy, the High-altitude Imaging Wind and Rain
84 Airborne Profiler (HIWRAP) radar and Hurricane Imaging Radiometer (HIRAD) (see Braun et
85 al. 2013 for descriptions) were moved onto the NASA Johnson Space Center WB-57f, which
86 was conducting a coincident Office of Naval Research (ONR) Tropical Cyclone Intensity (TCI)
87 mission utilizing a newly developed dropsonde system. The WB-57f is capable of flight
88 durations up to 6 hours, a range of approximately 3700 km, and altitudes of approximately 18.3
89 km (60,000 ft). Three science missions were flown by the WB-57f, which deployed from McDill
90 Air Force Base near Tampa, Florida.

91

92 **HS3 PAYLOADS**

93 The environmental GH carried three instruments, including the Scanning High-resolution
94 Interferometer Sounder (S-HIS), Cloud Physics Lidar (CPL) and Airborne Vertical Atmospheric
95 Profiling System (AVAPS).

96 S-HIS (details in Table 1; Revercomb 2015) is an advanced version of the HIS ER-2
97 instrument (Revercomb et al. 2003). Its noise levels are sufficiently low to allow cloud and
98 surface properties to be derived from each individual field of view. Temperature and water vapor
99 profiling can be performed on individual fields of view in the absence of significant clouds after
100 taking advantage of Principal Component Analysis to reduce noise levels (Antonelli et al, 2004).
101 The optical design is very efficient, providing useful signal-to-noise performance from a single
102 0.5-second dwell time. This allows imaging to be accomplished by cross-track scanning.
103 Onboard reference blackbodies are viewed via a rotating 45° scene mirror as part of each cross-
104 track scan, providing updated calibration information every 20-30 seconds.

105 CPL is a multi-wavelength backscatter lidar (McGill et al. 2002, 2003). CPL provides
106 information on the radiative and optical properties of cirrus, subvisual cirrus clouds, and aerosols
107 (McGill and Hlavka 2015). CPL utilizes a high-repetition rate, low-pulse energy transmitter and
108 photon-counting detectors and measures the total (aerosol plus Rayleigh) attenuated backscatter
109 as a function of altitude at each wavelength. For transmissive cloud/aerosol layers, the
110 extinction-to-backscatter parameter (S-ratio) can be directly derived using optical depth
111 measurements determined from attenuation of Rayleigh and aerosol scattering and using the
112 integrated backscatter. This permits unambiguous analysis of cloud optical depth since only the
113 lidar data is required. Using the derived extinction-to-backscatter ratio, the internal cloud
114 extinction profile can then be obtained (McGill et al 2003).

115 The AVAPS dropsonde system has been used for hurricane research for several decades
116 (Hock and Franklin 1999; Halverson et al. 2006). Dropsondes provide in-situ, high-vertical-
117 resolution profiles of basic atmosphere state variables – temperature, pressure, humidity, location,
118 and winds (Wick 2015). The GH dropsonde system was built by the National Center for

119 Atmospheric Research (NCAR) and carries up to 88 dropsondes per flight. In 2012, AVAPS
120 experienced significant radio frequency interference (RFI) problems that resulted in the loss of
121 data within a portion, and in some cases the majority, of some dropsonde profiles. The lowest
122 levels were most frequently impacted. The RFI issues were resolved before the 2013 campaign.

123 The over-storm payload consisted of the High-altitude Atmospheric Monolithic Microwave
124 Integrated Circuits Sounding Radiometer (HAMSR), HIWRAP, and HIRAD. A description of
125 these instruments can be found in Braun et al. (2013).

126 **SUMMARY OF HS3 FLIGHTS**

127 During the 3 years of deployments, HS3 flew 670 total flight hours and released 1426
128 dropsondes, including full 88-dropsonde loads on two flights (19-20 Sept. 2013 and 16-17 Sept.
129 2014). The GH flew 18 flights over 8 named storms over 3 years while the WB-57f flew 3 flights
130 over Hurricane Gonzalo in 2014 (Table 2).

131 In addition, the GH flew 2 non-developing systems (19-20 Sept. 2013 and 5-6 Sept. 2014)
132 that the National Hurricane Center (NHC) predicted had some potential to develop, 2 flights
133 specifically targeting the SAL (20-21 and 24-25 Aug., 2013), and 2 broad surveys of the Atlantic
134 Main Development Region (MDR) (22-23 and 28-29 Sept., 2014). Several additional flights
135 focused on instrument inter-comparisons. The 8-9 Sept. 2011 flight sampled an atmospheric river
136 event and was designed to inter-compare temperature and humidity profiles from AVAPS,
137 HAMSR, and S-HIS. The 13-14 Sept. 2011 and 30 Sept. 2014 flights were designed to compare
138 measurements from GH and National Oceanic and Atmospheric Administration (NOAA) G-IV
139 dropsondes. The 25 Sept. 2013 flight sampled precipitation in a mid-latitude frontal system to
140 compare measurements from the HIWRAP (GH) and IWRAP (NOAA P-3) radars. Flight tracks
141 for all flights, excluding the instrument inter-comparison and test flights, are shown in Fig. 1.

142 The most significant storms of the campaign were hurricanes Nadine (2012), Edouard
143 (2014), and Gonzalo (2014). Hurricane Nadine and Tropical Storm Gabrielle were the only
144 tropical cyclones to involve significant SAL interactions. Edouard and Gonzalo were the only
145 major hurricanes to occur during the 3 deployments. Hurricane Cristobal was sampled during its
146 extratropical transition.

147 **SCIENCE HIGHLIGHTS**

148 A number of future studies will provide detailed analyses of the observations obtained during
149 HS3. This section provides highlights of notable events and unique opportunities for research
150 enabled by the HS3 mission. The highlights include a period of apparent rapid intensification not
151 noted in the final NHC Tropical Cyclone Report for Hurricane Edouard, eyewall replacement
152 cycles in Hurricane Gonzalo, SAL interaction with Hurricane Nadine, and unprecedented storm
153 outflow measurements.

154

155 *Rapid intensification of Hurricane Edouard (2014)*

156 Four flights were conducted over Hurricane Edouard's lifecycle, including a period of rapid
157 intensification on 14-15 September 2014. Key measurements from the first two flights are
158 described below.

159 During HS3's first Edouard flight on 12 September, the GH was on station from
160 approximately 0430 to 1430 UTC. Edouard, then a tropical storm with maximum winds ~18.0-
161 20.5 m s^{-1} (35-40 kt), was experiencing moderate vertical wind shear ($\sim 7.7 \text{ m s}^{-1}$). Analysis of
162 the GH dropsondes showed a well-organized cyclonic circulation at 800 hPa (Fig. 2a) centered
163 on a region of intense convection and with relatively moist environmental conditions ($>70\%$) at
164 most locations. The precipitation and cloud cover suggested a high degree of asymmetry

165 associated with the westerly to northwesterly vertical wind shear. At 400 hPa (Fig. 2b), strong
166 west-northwesterlies brought very dry air over the southern portion of the storm, and the center
167 of circulation was displaced ~200 km to the northeast of the low-level center. A well-defined
168 outflow jet at 200 hPa (Fig. 2c) was evident on the northern side of the storm with anticyclonic
169 flow near the center.

170 During the 14-15 September flight, Edouard became vertically aligned (Fig. 2d-e) as the
171 vertical shear weakened. Although dry environmental air was present, particularly at mid-to-
172 upper levels (Fig. 2e), Edouard intensified to 41 m s^{-1} (80 kt) by 0000 UTC 15 September
173 according to the NHC final report (Stewart 2014) and developed a broad outflow jet at 200 hPa
174 on the western side of the storm (Fig. 2f) while maintaining a well-defined cyclonic circulation
175 close to the center.

176 During this second flight, the NHC rejected many of the AVAPS dropsonde observations of
177 surface pressure in the eye and eyewall, believing them to be too low compared to expected
178 values estimated from other sources. Here, we provide evidence to suggest that a brief period of
179 rapid intensification occurred over a 9-hour stretch, followed by a period of weakening as the
180 small eye broke down and reformed into a much larger eye as a result of an apparent eyewall
181 replacement cycle.

182 Dropsondes from the NOAA P-3 (NOAA43) and the GH provide estimates of Edouard's
183 intensity as measured by the storm's minimum central pressure. Table 3 lists data from 5
184 dropsondes released in the vicinity of the eye or inner edge of the eyewall during the period from
185 1500 UTC 14 September to 0430 UTC 15 September (2 dropsondes from the NOAA P-3 and 3
186 from the GH). All of the dropsondes, except the first P-3 drop, also measured strong surface
187 winds up to 44 m s^{-1} , suggesting that the dropsondes entered the low-level eyewall before

188 reaching the surface. The minimum central pressure of the storm is estimated by reducing the
189 dropsonde derived surface pressure 1 hPa per 5.1 m s^{-1} (10 kt) of wind speed (R. Pasch, NHC,
190 personal communication). Figure 3 shows the distribution of GH dropsondes in the inner-core
191 region from the entire flight, with dropsonde locations adjusted for storm motion and dropsonde
192 drift to a reference time of 0032 UTC 15 September (the time of the second center drop during
193 the GH flight). The lowest surface pressures and strongest winds were near the northern eyewall,
194 with weaker winds and higher pressures near the southern eyewall. Although the surface
195 pressures in the northern eyewall were lower than NHC estimates, there is consistency in the
196 low-pressure values that suggests valid measurements rather than spurious values.

197 The onset of Edouard's rapid intensification during this 14 September flight is consistent
198 with satellite imagery and NOAA P-3 dropsondes.

- 199 • 0845 UTC: An initial eye became apparent in GOES infrared imagery around.
- 200 • 1115 UTC: A convective burst developed on the northwestern side of the eye, moved
201 around to the southern side and expanded to the point of obscuring the eye (Fig. 4a-
202 b).
- 203 • 1500 UTC: As the cloud shield from the convective burst began to wrap around to the
204 eastern side of the circulation (1515 UTC, Fig. 4c), a NOAA P-3 dropsonde measured
205 a central pressure of 983 hPa with low wind speeds (Table 3), suggesting a dropsonde
206 very near the center.
- 207 • 1707 UTC: A P-3 dropsonde on the inner edge of the northeastern eyewall measured
208 a surface pressure of 984 hPa and a surface wind of 41 m s^{-1} . Reducing the minimum
209 surface pressure estimate by 8 hPa gives a central pressure of 976 hPa, a 7-hPa
210 decrease from just two hours earlier.

211 • 1715 UTC: A new, very small eye formed in the GOES imagery (Fig. 4d), suggesting
212 the onset of upper-level descent in the eye. Therefore, there is evidence of the onset
213 of rapid intensification in the P-3 and GOES data even before consideration of the
214 GH data.

215

216 During the period when Edouard had a very small eye (1715-0215 UTC), the GH released 2
217 dropsondes in the eye that entered the eyewall at low levels on the northern side of the eyewall.
218 The first GH center transect was a north-to-south pass, with the eye overflight occurring near
219 2104 UTC 14 September (Fig. 5a). GOES IR imagery (Fig. 4e) showed a very small eye with the
220 GH passing between two regions of higher cloud-top heights (inferred from the colder cloud-top
221 temperatures) associated with deep convection. Brightness temperatures from S-HIS (Fig. 5a)
222 indicated that the 2104 UTC dropsonde was released on the eastern side of the eye, with the
223 dropsonde gradually moving around to the northern eyewall at low levels. This dropsonde
224 measured a surface pressure of 971.7 hPa and an estimated 10-m wind speed of 41.7 m s^{-1} (81 kt).
225 Adjusting for the high wind speed gives a central pressure estimate of 963.6 hPa, suggesting a
226 ~13-hPa drop in pressure in 4 hours since the last P-3 drop and a 19-hPa drop since 1500 UTC.

227 Although the GOES imagery suggested significant axisymmetrization of the cloud field
228 during RI, the storm circulation remained highly asymmetric. Figure 5b shows a vertical cross
229 section of storm-relative tangential winds obtained from dropsondes along this north-to-south
230 flight leg, with the 2104 UTC dropsonde closest to the storm center. The dropsonde spacing in
231 the inner-core region was insufficient to resolve the eyewall and eye, but the figure clearly shows
232 the strong tangential winds on both the northern and southern sides of the center. Strong radial
233 inflow (Fig. 5c) occurred in the boundary layer on the northern side of the storm while weak

234 outflow was present south of the center. A prominent outflow jet was present in the 8.5-15 km
235 altitude layer to the north of the center, while weaker outflow near 11 km altitude occurred to the
236 south, consistent with the 200-hPa wind analysis in Fig. 2f. Dry air (Fig. 5d) was located about
237 2° (~ 200 km) to the south and 3° (~ 300 km) to the north of the center of the storm¹.

238 During the second center overflight at 0032 UTC 15 September (see corresponding GOES
239 imagery for 0045 UTC in Fig. 4f), a dropsonde released in the upper eye fell into the northern
240 eyewall at low levels, measuring a surface pressure of 967.2 hPa and a near-surface wind of 44
241 m s^{-1} (86 kt), suggesting an estimated central pressure of 958.6 hPa. Figure 6 shows the timing of
242 the 0032 UTC dropsonde relative to the cloud attenuated backscatter from CPL and real-time
243 temperatures from S-HIS. The 0032 UTC dropsonde was clearly released into the eye and the
244 CPL (Fig. 6) and dropsonde data (not shown) both suggest that the dropsonde entered the inner
245 edge of the eyewall near 800 hPa.

246 Edouard's small eye persisted continuously in GOES imagery until 0215 UTC, after which
247 time the cloud structure gradually became more disorganized (Fig. 4g-h), suggesting a
248 reorganization of the eyewall. By 0900 UTC, a new eye reformed in the upper-level clouds
249 (shown in Fig. 4i at 1345 UTC), but with a much larger radius ($\sim 0.9^{\circ}$) than seen earlier ($\sim 0.2^{\circ}$,
250 Fig. 4e). The last GH dropsonde near the center at 0428 UTC measured a higher pressure in the
251 northern eyewall area (estimated central pressure of 963 hPa), suggesting a weakened intensity
252 coincident with the apparent eyewall replacement cycle.

253 Based upon the P-3 and GH dropsondes, an estimated time series of minimum central
254 pressure is shown in Fig. 7 along with the NHC best-track pressures (Stewart 2014). The aircraft

¹ Comparisons between S-HIS and AVAPS suggest a dry bias in the AVAPS data above 400 hPa, so relative humidities with respect to ice above ~ 8 km should be closer to saturation within the cloud system.

255 data, combined with the GOES imagery, suggest that during the period of the P-3 flight and the
256 first half of the GH flight, Edouard transitioned from an asymmetric system during a major
257 convective burst to a more symmetric system (in the GOES cloud-top field, but not the wind
258 field; Fig. 5) with a well-defined but very small eye, and that during this time rapid
259 intensification occurred as the central pressure decreased from 983 to 958 hPa. This short-
260 duration RI phase suggests a brief period at near category-3 intensity compared to the best-track
261 time series and could not be detected by the once-a-day NOAA P-3 flights², indicating the added
262 value of the long-duration GH. The 0032 UTC dropsonde-derived central pressure is consistent
263 with, but somewhat lower than, some of the satellite-based intensity estimates (red dots) in Fig. 7.
264 The intensification just as quickly came to an end when the initially small eye broke down and
265 got replaced by a much larger eye. Intensification resumed with the formation of the new and
266 larger eye, leading to a second period of category-3 intensity.

267

268 *Tropical Cyclone-SAL interaction (Nadine)*

269 Hurricane Nadine (2012) was HS3's best case for examining the interaction of a tropical
270 cyclone with the SAL. Nadine originated from a tropical wave that emerged from the West
271 African coast on 7 September in association with a small dust outbreak to its north. As the wave
272 moved westward on 9 September, a large and more intense dust outbreak exited the Sahara and
273 advanced toward the tropical disturbance. Nadine became a tropical depression on 10 September
274 (Fig. 8a) and by 11 September (Fig. 8b) the SAL outbreak was encroaching on the cloud
275 system's northern and eastern sides. Nadine became a tropical storm at 0000 UTC 12 September
276 during the middle of the first GH flight. Dropsonde data were collected in the western part of the

² There were no Air Force Hurricane Hunter flights during Edouard.

277 storm, but were discontinued midway through the flight after a dropsonde became jammed in the
278 launcher. As a result, no dropsondes were obtained in the eastern part of the storm and within the
279 SAL.

280 Neither dropsonde nor CPL data indicated the presence of SAL air in the northwestern
281 quadrant of the storm during the 11-12 September flight (northern portions of the 2nd and 3rd
282 flight legs from the left on the western side of the storm in Fig. 8b). With dropsondes disabled,
283 CPL and S-HIS detected a deep layer of SAL air (Fig. 9) along the northern portions of the 4th
284 and 5th flight legs in Nadine's northeastern quadrant. Upon traversing north of Nadine's upper
285 cloud shield (~0100 UTC, Fig. 9a), CPL detected a deep dust layer with a top near 530 hPa. In
286 the dust region, S-HIS retrievals (Fig. 9b) indicated very hot and dry (0-20% relative humidity)
287 air between 850-700 hPa and cooler and more moist conditions (~50%) near the top of the dust
288 layer, consistent with Carlson and Prospero (1972), Messenger et al. (2009), Ismail et al. (2010),
289 and Braun (2010).

290 The 14-15 September flight occurred as Nadine was moving northward near 54°W with the
291 SAL encroaching on its eastern and northern sides (Fig 8c-e). Vertical shear estimates from the
292 Statistical Hurricane Intensity Prediction System (SHIPS, DeMaria and Kaplan 1994, 1999;
293 DeMaria et al. 2005) indicated 850-200 hPa vertical wind shear (not shown) changing from weak
294 northwesterly shear on 12 September to west-southwesterly shear of 12-15 m s⁻¹ by 0000 UTC
295 15 September. During the period of weak shear on 12 September, Nadine intensified 12.9 m s⁻¹
296 in 24 hours, 2.6 m s⁻¹ below the threshold for rapid intensification (Kaplan and DeMaria 2003).
297 With the onset of stronger vertical shear on 13 September, negligible intensification occurred
298 from 0000 UTC 13 to 1200 UTC 14 September. A series of convective bursts and coincident
299 frequent lightning during the GH flight between 1400-2100 UTC 14 September helped Nadine

300 just reach hurricane intensity by 1800 UTC 14 September before strong environmental westerlies
301 pushed Nadine quickly eastward over cooler waters.

302 Global Hawk dropsonde observations of equivalent potential temperature (θ_e) and storm-
303 relative winds spanning the period 17 UTC 14 September to 08 UTC 15 September are shown in
304 Fig. 10. At 800 hPa (Fig. 10a), low θ_e air associated with the SAL is found on the eastern side of
305 the storm wrapping around the northern side, consistent with MODIS observations over
306 preceding days, with a principal rainband marking the boundary between SAL in the outer
307 environment and more moist conditions in the inner core. The dry SAL air is on the downshear
308 side of the storm and so may have had a pathway into the inner-core circulation on the north
309 (downshear) side of the storm (Willoughby et al. 1984; Marks et al. 1992; Braun et al. 2006;
310 Riemer and Montgomery 2011). At 400 hPa (Fig. 9b), very dry westerly flow associated with the
311 strong environmental shear impinged on the entire western flank of the storm, with the driest air
312 wrapping around the southern side of the circulation. It is not yet possible to determine the
313 impact of the SAL and upper-level dry air from these observations. However, ensemble
314 simulations with the Weather Research and Forecasting model with coupled aerosol-cloud-
315 radiation physics are being used to quantify the role of the SAL and dry air in this case.

316

317 *Tropical cyclone outflow structure*

318 Tropical cyclone outflow is a prominent part of the secondary circulation and its
319 thermodynamic structure plays a key role in hurricane maximum potential intensity (MPI)
320 theory. Emanuel (1986, 1997) derived expressions for MPI that depended on a constant outflow
321 temperature with the outflow occurring above the tropopause (Emanuel and Rotunno 2011). The
322 model assumed that outflow streamlines asymptotically approach altitudes at which their

323 saturated entropy values match those of the undisturbed environment so that outflow structure is
324 determined by environmental stratification. However, Emanuel and Rotunno (2001) used
325 simulated storms to demonstrate that outflow stratification is instead the result of internal
326 dynamics and small-scale turbulence that limits the Richardson number (Ri) to a critical value
327 needed for the onset of that turbulence.

328 Molinari et al. (2014) examined NOAA G-IV dropsonde data and identified three situations
329 that produce low Ri in outflow regions. The first situation was just beneath the outflow-layer
330 stratiform cloud deck where sublimation cooling produced high stability near cloud base and a
331 neutral or unstable lapse rate and low Ri just beneath the stable layer. In the second case, low Ri
332 occurred above cloud base where radiative heating (cooling) near cloud base (top) resulted in
333 sufficiently low stability to cause low Ri values. Vertical wind shear was not a contributor to the
334 low Ri in either of these cases. The third situation occurred outside the central dense overcast in
335 association with strong vertical wind shear at the base of the outflow layer.

336 The G-IV dropsondes typically provide data only below 12-13 km and therefore miss the
337 upper part of the outflow layer and the lower stratosphere. During HS3, the GH provided
338 relatively high-density coverage over a large extent of the outflow layer from the lower
339 stratosphere to the surface. An example of outflow layer structure was shown in Fig. 5. To the
340 north of the center, outflow $>4 \text{ m s}^{-1}$ extended vertically between ~ 8.5 to 15 km and from the
341 eyewall to more than 8° ($\sim 770 \text{ km}$) from the center. The strongest outflow occurred just beneath
342 cloud top near the northern eyewall, but beyond a radius of $\sim 200 \text{ km}$, outflow often extended
343 above and beyond regions of cloudiness. In addition to inflow beneath the outflow layer, another
344 region of strong inflow existed in the lower stratosphere above the outflow layer and extended all
345 the way inward to the storm center. Tangential velocities in the outflow layer transitioned from

346 cyclonic flow beneath cloud top out to $\sim 28^\circ\text{N}$ (~ 250 km radius) to strong anticyclonic flow
347 northward of 30°N (~ 400 km radius). A very shallow layer of strong anticyclonic velocities
348 occurred at the tropopause at the transition from upper-tropospheric outflow to lower-
349 stratospheric inflow.

350 Figure 11 shows results from a calculation of the Richardson number using the data shown
351 in Fig. 5. In unsaturated regions (taken here as regions with relative humidity $< 95\%$), Ri is
352 estimated from $Ri = N^2/S^2$, where $N^2 = (g/\theta_v)(\Delta\theta_v/\Delta z)$, $S^2 = [(\Delta U)^2 + (\Delta V)^2]/(\Delta z)^2$, θ_v
353 is the virtual potential temperature, U and V are the zonal and meridional wind components,
354 respectively, and z is geopotential height. Where relative humidity $> 95\%$, a moist Ri [Eqs. A1-
355 A4 of Molinari et al (2014)] derived from Durran and Klemp (1982) is used. In addition to the
356 very low moist Ri values in the inner core below 6 km associated with both low stability (N^2 , Fig.
357 11b) and moderate shear (S , Fig. 11c), very low Ri (< 0.25) are found primarily above the outflow
358 layer just above the tropopause. This layer is characterized by high stability and very strong
359 shear, the latter being responsible for the low Ri values. This layer of low Ri would not be
360 detectable from G-IV dropsondes because of their lower release altitude. The dropsonde profiles
361 near 23.7° (at 6- and 7.5-km altitude) and 29.7°N (at 7 km) exhibit sublimation-induced unstable
362 layers a few hundred meters in depth associated with intrusions of dry air beneath cloud base at
363 mid levels similar to that seen by Molinari et al. (2014). Within the outflow layer, some regions
364 with $Ri < 1$ are found, particularly near the northern eyewall, and are often associated with low
365 stability in the outflow layer. However, unlike in Molinari et al. (2014), moderate vertical wind
366 shear usually also contributes significantly to the low Ri values there.

367 **SUMMARY**

368 Along with the NASA GRIP campaign, HS3 has demonstrated the unique contributions of
369 the Global Hawk for conducting hurricane science research, taking advantage of the long
370 duration, high altitude, and heavy payload capabilities of the aircraft. While GRIP produced the
371 first-ever GH flights, the GH was launched from NASA's Armstrong Flight Research Center in
372 Southern California, which greatly reduced on-station times for storms eastward of the Gulf of
373 Mexico and prevented flights east of about 66°W. HS3 paved the way for flights from the East
374 Coast and demonstrated the use of mobile trailers for controlling the GH and its payload. These
375 East Coast deployments allowed flights of most systems in the Atlantic, particularly for storms
376 not accessible by operational manned aircraft. HS3 also showed that the GH can conduct
377 surveillance over extended periods of any tropical weather system in the Atlantic/Caribbean
378 basin. Tasking of the UAS can also be adjusted in real-time to account for changing storm
379 conditions.

380 Over the course of the HS3 mission, NASA developed key relationships with NOAA, the
381 Federal Aviation Administration, and Department of Defense to implement and improve
382 operational procedures and demonstrate the scientific value of the GH data sets, leading to
383 efforts by NOAA's Sensing Hazards with Operational Unmanned Technologies (SHOUT)
384 program to examine the operational forecasting utility of the GH platform and instruments.

385

386 *Acknowledgements*

387 The HS3 mission was funded by NASA's Earth Venture Suborbital program at NASA
388 Headquarters. NOAA P-3 dropsonde data were provided by NOAA's Physical Oceanography
389 Division (PHOD) of Atlantic Oceanographic and Meteorological Laboratory. Dennis Hlavka and

390 John Yorks from Goddard provided the CPL data. Peter Black, James Doyle, and Jon Moskaitis
391 provided valuable discussions related to storm outflow.

392

393 **Sidebar: Inner-Core Structure During Hurricane Gonzalo.**

394 The three flights of the WB-57f over Hurricane Gonzalo (Fig. 1d and Table 2) provided
395 inner-core measurements during an interesting period when the storm was moving
396 northwestward and then north-northeastward around a ridge in the central Atlantic. The
397 storm intensified from category 3 on 15 October to category 4 on 16 October, when it had a
398 minimum central pressure of 940 hPa and maximum winds of 125 kt. An eyewall
399 replacement cycle occurred on the 15th, causing the storm to weaken briefly before
400 recurving. Gonzalo again had a double eyewall late on 16 October, also concurrent with a
401 weakening of the storm.

402 Figure S1 shows the HIWRAP (Heymsfield 2015) reflectivity structure highlighting the
403 double eyewall structure on 17 September 2014. Gonzalo had an asymmetrical structure
404 with its cloud shield spreading to the north and east. The heavier precipitation in the cross
405 section is on the northwest side of the storm. This cross section and other similar passes
406 over the three days are being analyzed for both precipitation and wind structure similar to
407 what has been done in previous HIWRAP studies (Guimond et al. 2014; Didlake et al. 2014).

522 Figure 1. Graphic summary of the HS3 Atlantic tropical cyclone and SAL flights. Panels show
523 GH flight tracks for the (a) 2012 campaign, (b) 2013 campaign, and (c) 2014 campaign, while
524 (d) shows the 2014 WB-57f flight tracks over Hurricane Gonzalo.

525 Figure 2. (a and b) Dropsonde-derived 800 hPa and 400 hPa relative humidity and (c) 200 hPa
526 ground-relative wind speed (colored circles) from the 11-12 September 2014 flight. Color bars
527 for relative humidity and wind speed are shown along the bottom of the figure. Wind barbs (full
528 barb, 5 m s^{-1} ; half-barb, 2.5 m s^{-1} ; flags, 25 m s^{-1}) show storm-relative winds at the respective
529 altitudes. Dropsonde locations account for dropsonde drift and storm motion, with positions
530 adjusted to a reference time of 0900 UTC 12 September. Data superimposed on GOES infrared
531 imagery (IR) at 0845 UTC and SSMI/S 91 GHz polarization corrected temperature [color scale
532 in (b)] at 0849 UTC 12 September. (d-f) Same as (a-c), but for a reference time of 0032 UTC 15
533 September and superimposed on GOES IR imagery at 0045 UTC 15 September. Satellite
534 imagery is from the Naval Research Laboratory Tropical Cyclone web page
535 (<http://www.nrlmry.navy.mil/TC.html>).

536 Figure 3. Plots of (a) surface pressure and (b) estimated 10-m ground-relative wind speed for the
537 14-15 September 2014 GH flight. Wind barbs (full barb, 5 m s^{-1} ; half-barb, 2.5 m s^{-1} ; flags, 25 m
538 s^{-1}) show storm-relative winds. Dropsonde positions are adjusted to a reference time of 0032
539 UTC 15 September using the observed position and time of the near-surface observations and an
540 estimated storm motion based on the NHC-determined best track information.

541 Figure 4. GOES Infrared imagery (see color scale at bottom) from the Naval Research
542 Laboratory tropical cyclone website for (a) 1115, (b) 1315, (c) 1515, (d) 1715, and (e) 2115 UTC
543 14 September; and (f) 0045, (g) 0315, (h) 0715, and (i) 1315 UTC 15 September 2014.

544 Figure 5. (a) S-HIS brightness temperatures (color shading, K) for the $895\text{-}900\text{ cm}^{-1}$ channel. The
545 eye of Edouard is labeled “Eye” near the warm brightness temperatures associated with the low
546 clouds in the eye. The black dashed line shows the approximate flight path (line segments
547 through dropsonde points only). Short curved line segments indicate dropsonde horizontal
548 trajectories, with the release point coinciding with the flight path. Dropsonde times (UTC) are
549 indicated. (b) Tangential velocity, (c) radial velocity, and (d) relative humidity with respect to
550 water for temperatures $\geq 273.15\text{K}$ and with respect to ice at colder temperatures (color shading)
551 derived from dropsonde data between 1935-2207 UTC 14 September. Dropsonde locations are
552 indicated by vertical lines. Grey shading in right panels shows CPL attenuated backscatter (ABS,
553 $\text{km}^{-1}\text{ sr}^{-1}$) multiplied by 100. Vertical arrow in (b) indicates the location of the center dropsonde
554 at 2104 UTC.

555 Figure 6. CPL attenuated backscatter ($\times 100$) and S-HIS real-time retrieved air temperature for
556 the period 0020-0045 UTC 15 September during a transit over the storm from northeast to
557 southwest of the center. Vertical dashed line shows the location of the 0032 UTC 15 September
558 dropsonde.

559 Figure 7. Time series of NHC best-track (black line) central pressure and operational intensity
560 estimates (red circles, from satellite and aircraft). The blue line indicates estimated central
561 pressures from P-3 (black circles) and GH (open circles) dropsondes. Orange and purple lines

562 along the bottom of the figure indicate on-station times for NOAA P-3s and GH, respectively.
563 Text indicates significant events during storm evolution.

564 Figure 8. MODIS daily cloud and aerosol optical depth (colors) images show the evolution of the
565 SAL outbreak near Hurricane Nadine on the indicated days. The flight track for the 11-12
566 September flight is shown in (b) and for the 14-15 September flight in (e). MODIS imagery
567 obtained from the NASA Worldview web page (<https://earthdata.nasa.gov/labs/worldview/>).

568 Figure 9. (a) CPL aerosol backscatter ($\times 100 \text{ km}^{-1} \text{ sr}^{-1}$) showing the dust layer north of Nadine
569 along the northern portions of the 5th and 6th north-south oriented flight legs (from left to right in
570 Fig. 8b) during the 11-12 September 2012 flight. S-HIS (b) relative humidity and (c) temperature
571 perturbation for the same flight segment. Temperature perturbations are derived by removing the
572 average temperature from 2000 UTC 11 September to 0600 UTC 12 September. The horizontal
573 line marks the top of the dust layer, and the vertical lines separate times of nearly clear skies
574 (0100-0149 UTC) from times with upper-level cloud cover. There is a reversal in the
575 temperature anomalies below 400 hPa and much higher low-level relative humidity before 0100
576 UTC and after 0149 UTC, suggesting possible retrieval biases caused by upper-level clouds.
577 Vertical arrows indicate the times of aircraft turns, first from northbound to eastbound, second
578 from eastbound to southbound.

579 Figure 10. Equivalent potential temperature (colored circles) and storm-relative wind barbs (full
580 barb, 5 m s^{-1} ; half-barb, 2.5 m s^{-1} ; flags, 25 m s^{-1}) at (a) 800 hPa and (b) 400 hPa superimposed on
581 the GOES infrared imagery at 0015 UTC 15 September 2012. Dropsonde locations account for
582 dropsonde drift and storm motion, with positions adjusted to a reference time of 0000 UTC 15
583 September. Color bars indicate θ_e values (K) corresponding to the dropsonde data in each panel.

584 Figure 11. Plots of (a) bulk Richardson number and CPL attenuated backscatter ($\times 100 \text{ km}^{-1} \text{ sr}^{-1}$),
585 (b) Brünt-Vaisala frequency, N^2 (s^{-2}), and (c) vertical wind shear, S (s^{-1}), for the Edouard cross
586 section shown in Fig. 5. In (a), the 45% relative humidity contour is shown to indicate an
587 approximate boundary of very dry air. In (b), contours are of potential temperature at 4 K
588 intervals while in (c) contours show outflow regions with radial velocity at 4 m s^{-1} intervals
589 starting at 4 m s^{-1} .

590 Figure S1. Hurricane Gonzalo on 17 September 2014 as observed from the HIWRAP Ka-band
591 frequency as the storm was approaching Bermuda. Vertical cross section (top) and horizontal
592 cross sections at 2.7, 5.0 and 7.3 km altitude (bottom panels) reconstructed from HIWRAP
593 conical scanning outer beam. Both inner and outer eyewalls are observed at 110 and 160 km, and
594 40 and 250 km, respectively. The Ka-band data shown has higher resolution than the Ku-band
595 and is more sensitive to light precipitation at upper levels in the eyewall, but suffers more
596 attenuation in heavy rain near the surface.

597

598

599 **Table 1.** Instrument characteristics for the environmental and over-storm GH payloads.

600

Instrument	Spectral Bands	Spatial Resolution (FOV), Profile Resolution	Retrieved Measurement Precision	Data Products
Environmental Payload				
CPL	355, 532, and 1064 nm, with depolarization at 1064 nm	100 m, 30 m vertical	Optical depth, 11-25%	Profiles of calibrated attenuated backscatter; cloud/aerosol layer boundaries; cloud/aerosol optical depth, extinction, and depolarization; color ratio
AVAPS	N/A	N/A, 0.5 s vertical	N/A	Quality controlled vertical profiles of temperature, pressure, humidity, wind speed and direction
S-HIS	Continuous spectral coverage 3.3 to 16.7 μm @ 0.5 cm^{-1}	0.1 radians (11 samples cross track), 1-3 km vertical	Temperature < 1K, water vapor < 15%	IR temperature spectra, IR cloud-top temperature, cloud-top height, optical depth, effective radius, water skin temperature. Atmospheric temperature and water vapor profiles in clear-sky conditions
Over-Storm Payload				
HAMSR	8 channels between 50-60 GHz, 10 between	2 km horizontal, 1-3 km vertical	2 K for temperature, 15% for water	Calibrated geolocated brightness temperatures; vertical profiles of temperature, water vapor,

	113-118 GHz, and 7 between 166-183 GHz		vapor, 25% for liquid water	and liquid water; precipitation structure
HIRAD	4, 5, 6, 6.6 GHz	Horizontal resolution of 1.6 km (6.6 GHz) to 2.5 km (4 GHz) at nadir from 20 km altitude	1-5 m s ⁻¹ for wind speed	Brightness temperatures at 4 C- band frequencies; surface wind speed, rain rate
HIWRAP	13.35, 13.91, 33.72, 35.56 GHz	0.42 km (Ka) and 1.0 km (Ku) horizontal, 60 m vertical	Horizontal winds, < 2 m s ⁻¹	Calibrated reflectivity, platform- corrected Doppler velocity, surface return, 3-D reflectivity fields and horizontal winds, ocean surface winds

Table 2. Summary of HS3 flights. AV=Air Vehicle. TS=Tropical Storm. TD=Tropical Depression. ET=Extratropical. NPP=NPOES Preparatory Project. MDR=Main Development Region.

Date	GH	Storm/Event	Description/comments
2011			
8-9 Sep	AV-6	Pacific atmos. river	North-south cross section from 50° to 10°N along 154°W for intercomparison of AVAPS, S-HIS, and HAMSRS.
13-14 Sep	AV-6	No storm	Intercomparison of AVAPS and NOAA G-IV dropsondes in warning area off Tampa, FL.
2012			
6-7 Sep	AV-6	Hurr. Leslie	Outflow structure of Leslie during transit to WFF.
11-12 Sep	AV-6	TS Nadine	Nadine became a TS with SAL air along northern side. AVAPS failed mid-way through flight. Reduced CPL sensitivity due to cold instrument temperature.
14-15 Sep	AV-6	Hurr. Nadine	Nadine became a hurricane in high-shear conditions, SAL air wrapped partly around northern side. Reduced CPL sensitivity due to cold instrument temperature.
19-20 Sep	AV-6	TS Nadine	Nadine weakened to TS strength near the Azores. CPL issue resolved.
22-23 Sep	AV-6	TS Nadine	Nadine became a TS again after 1 day post-tropical.
26-27	AV-6	TS Nadine	Nadine moved southward, convection intensified 2 days prior

Sep			to re-intensification to hurricane strength.
6 Oct	AV-6	No storm	Underflew both NPP and Aqua, no dropsondes available.
5-6			
Nov	AV-1	ET Cyclone	Test flight of AV-1 in an extratropical cyclone in the Pacific.
2013			
20-21			Environmental sampling of shallow former TS Erin and SAL air mass. AVAPS released only 15 of 44 planned drops after it lost power from the aircraft.
Aug	AV-6	Ex-Erin/SAL	
24-25			
Aug	AV-6	SAL	SAL flight in weak African wave disturbance.
29-30			
Aug	AV-6	Pre-Gabrielle	Pre-Gabrielle African wave with SAL air.
3-4			
Sep	AV-1	Pre-Gabrielle	Measurement of convective structure of Pre-Gabrielle and adjacent convective disturbance.
4-5			
Sep	AV-6	TS Gabrielle	Environmental sampling of TS Gabrielle and adjacent convective disturbance.
7-8			
Sep	AV-6	Ex-Gabrielle	Potential redevelopment of former TS Gabrielle.
15-16			
Sep	AV-1	Hurr. Ingrid	Precipitation/wind measurements in Hurr. Ingrid. Flight cut short due to cold fuel temperatures.
16-17			
Sep	AV-6	TS Humberto	Redevelopment of TS Humberto. Hybrid low-level warm-core/upper-level cold-core structure observed.
19-20	AV-6	Invest A95L	Environmental measurements of Invest A95L that, despite a

Sep			good low-level circulation and moisture, failed to develop into a tropical depression.
25 Sep	AV-1	ET cyclone	Precipitation system sampling in coordination with NOAA43 for HIWRAP/IWRAP intercomparison.
2014			
26-27 Aug	AV-6	Hurr. Cristobal	AV-6 transit and science flight over Hurricane Cristobal.
28-29 Aug	AV-6	Hurr. Cristobal	Hurricane Cristobal extratropical transition.
2-3 Sep	AV-6	TS Dolly	TS Dolly just prior to landfall along Mexican coast.
5-6 Sep	AV-6	SAL A90L	Invest A90L and its interaction with the SAL.
11-12 Sep	AV-6	TD6/TS Edouard	TS stage with possible nascent eye. CPL data loss due to disk failure.
14-15 Sep	AV-6	Hurr. Edouard	Four overflights near the center, rapid intensification.
16-17 Sep	AV-6	Hurr. Edouard	Mature stage, beginning of secondary eyewall replacement.
18-19 Sep	AV-6	Hurr./TS Edouard	Rapid weakening just west of the Azores.
22-23 Sep	AV-6	MDR Survey	Box from 60° to 21.5°W, eastbound at 19°N, westbound at 14°N.

28-29			
Sep	AV-6	MDR Survey	Zig-zag pattern between 55°-27°W, 13-18°N.
30			
Sep	AV-6	No storm	Intercomparison of AVAPS and G-IV dropsondes and flight-level winds during GH transit to AFRC.
15	WB-		
Oct.	57f	Hurr. Gonzalo	Two overpasses of Cat 3 intensity storm.
16	WB-		
Oct.	57f	Hurr. Gonzalo	Three overpasses of Cat 4 intensity storm.
17	WB-		
Oct.	57f	Hurr. Gonzalo	Two overpasses of Cat 3-4 intensity storm.

605

Table 3. NOAA P-3 and NASA GH dropsonde data near or within the eye of Edouard during 14-15 September. Estimates of the minimum sea-level pressure at the storm center are obtained by reducing the observed surface pressure by 1 hPa per 5.1 m s^{-1} of 10-m level wind speed. Wind speeds are reduced to 10 m following Table 3 of Franklin et al. (2003).

Aircraft/ Day/Time (UTC)	Release Location Relative to Storm Center	Psf (hPa)	Wind Speed Closest to 10- m Level (m s^{-1})	Geopotential Height of Wind (m)	Estimated 10- m Wind Speed (m s^{-1})/(kt)	Estimated MSLP (hPa)
P3/14/1500	Eye center	982.8	2.6	9	2.6/5.1	982.8
P3/14/1707	NE eye/eyewall	984.3	41.0	10	41.0/79.7	976.3
GH/14/2104	E eye/eyewall	971.7	45.3	33	41.7/81.1	963.6
GH/15/0032	Eye center	967.2	44.2	8	44.2/86.0	958.6
GH/15/0428	SE eye/eyewall	970.7	43.0	10	43.0/83.6	962.3

606

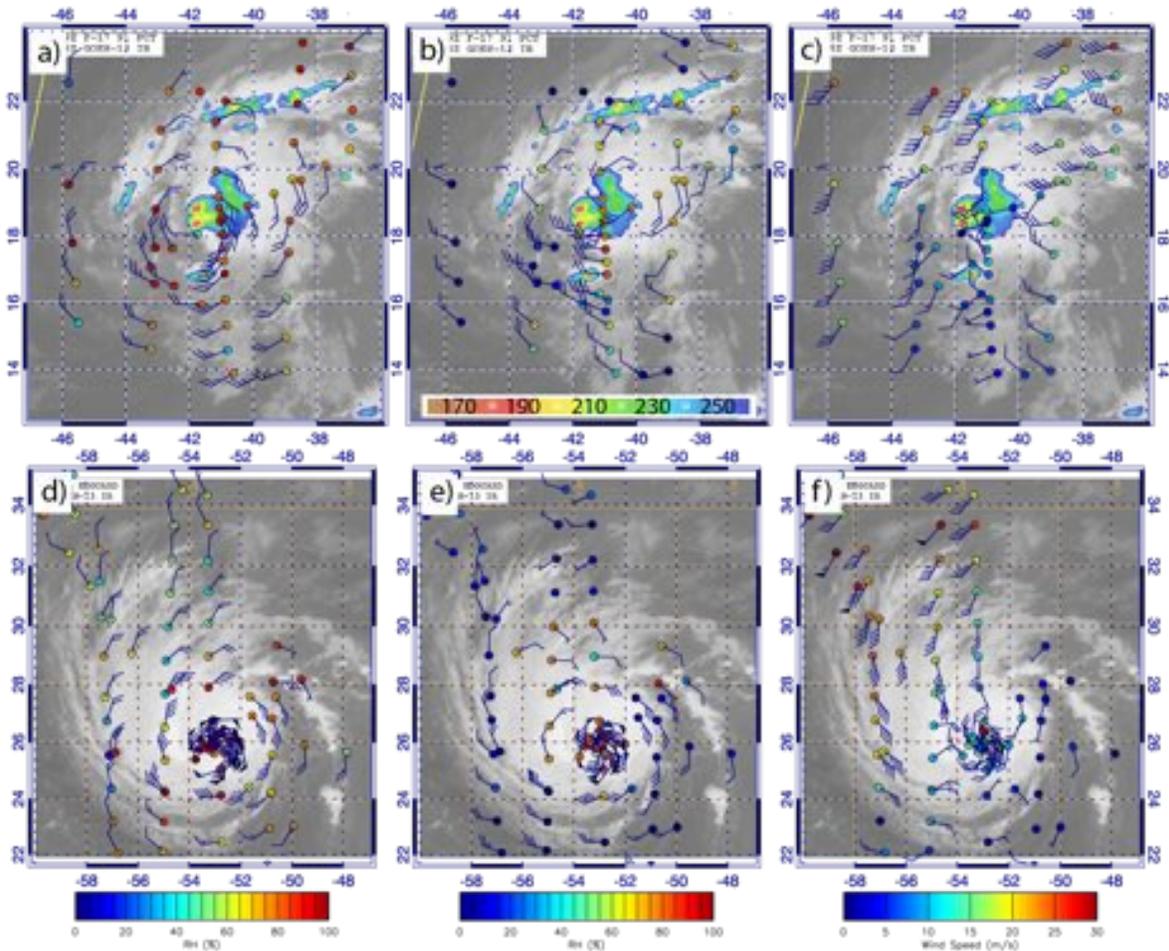

607

608

609 Figure 1. Graphic summary of the HS3 Atlantic tropical cyclone and SAL flights. Panels show
 610 GH flight tracks for the (a) 2012 campaign, (b) 2013 campaign, and (c) 2014 campaign, while
 611 (d) shows the 2014 WB-57f flight tracks over Hurricane Gonzalo.

612

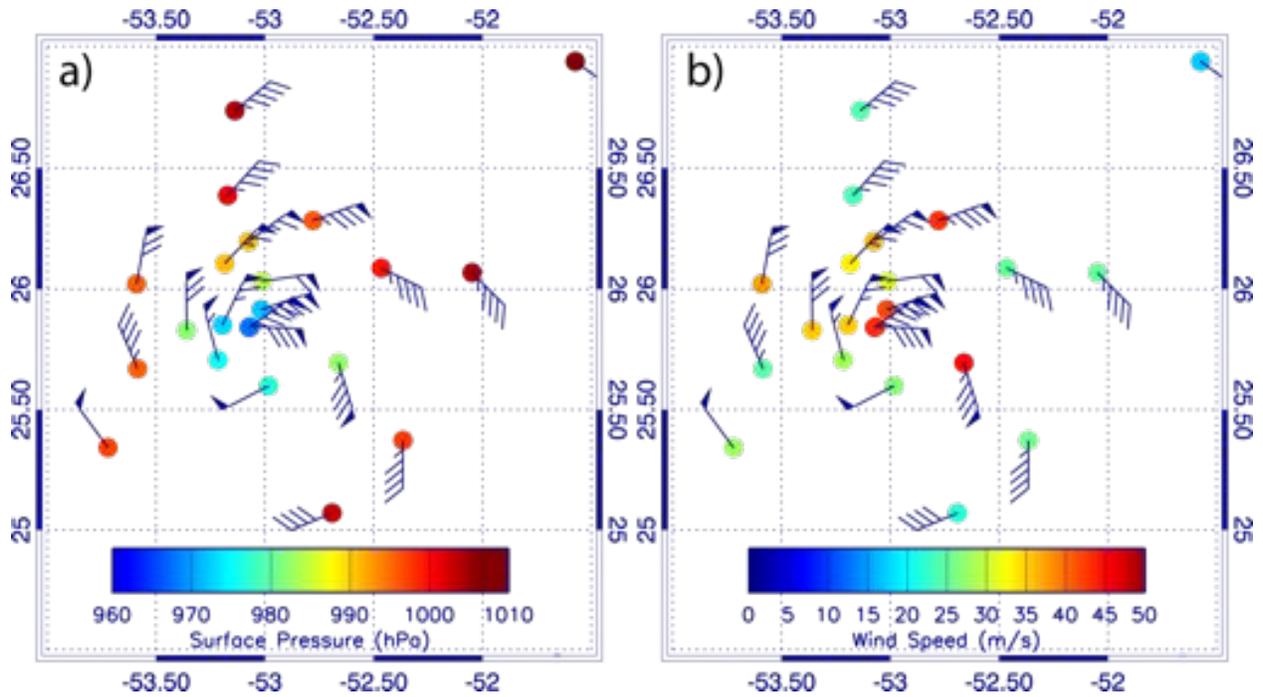

613

614 Figure 2. (a and b) Dropsonde-derived 800 hPa and 400 hPa relative humidity and (c) 200 hPa
 615 ground-relative wind speed (colored circles) from the 11-12 September 2014 flight. Color bars
 616 for relative humidity and wind speed are shown along the bottom of the figure. Wind bars (full
 617 barb, 5 m s^{-1} ; half-barb, 2.5 m s^{-1} ; flags, 25 m s^{-1}) show storm-relative winds at the respective
 618 altitudes. Dropsonde locations account for dropsonde drift and storm motion, with positions
 619 adjusted to a reference time of 0900 UTC 12 September. Data superimposed on GOES infrared
 620 imagery (IR) at 0845 UTC and SSMI/S 91 GHz polarization corrected temperature [color scale
 621 in (b)] at 0849 UTC 12 September. (d-f) Same as (a-c), but for a reference time of 0032 UTC 15
 622 September and superimposed on GOES IR imagery at 0045 UTC 15 September. Satellite

623 imagery is from the Naval Research Laboratory Tropical Cyclone web page
624 (<http://www.nrlmry.navy.mil/TC.html>).

625

626

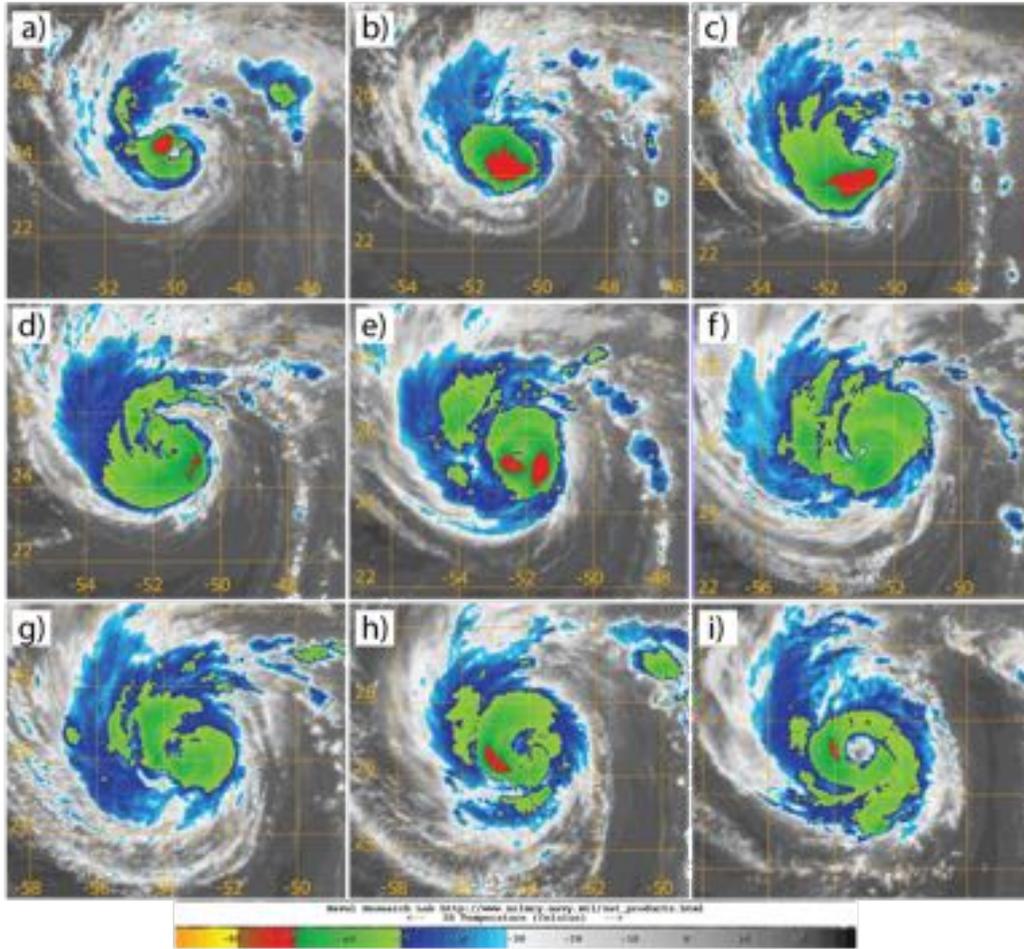

627

628 Figure 3. Plots of (a) surface pressure and (b) estimated 10-m ground-relative wind speed for the
629 14-15 September 2014 GH flight. Wind barbs (full barb, 5 m s^{-1} ; half-barb, 2.5 m s^{-1} ; flags, 25 m
630 s^{-1}) show storm-relative winds. Dropsonde positions are adjusted to a reference time of 0032
631 UTC 15 September using the observed position and time of the near-surface observations and an
632 estimated storm motion based on the NHC-determined best track information.

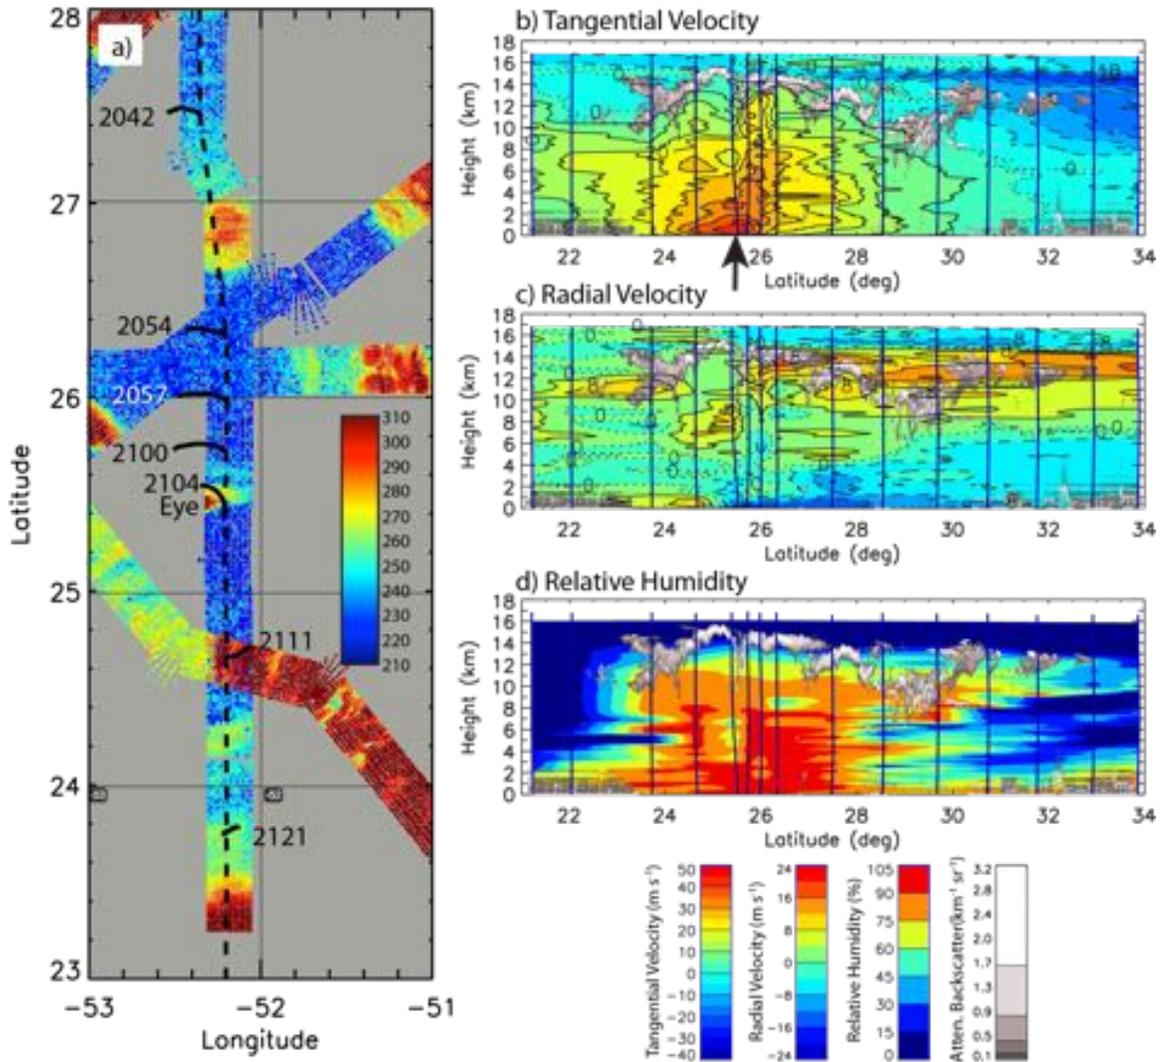

633

634

635 Figure 4. GOES Infrared imagery (see color scale at bottom) from the Naval Research
636 Laboratory tropical cyclone website for (a) 1115, (b) 1315, (c) 1515, (d) 1715, and (e) 2115 UTC
637 14 September; and (f) 0045, (g) 0315, (h) 0715, and (i) 1315 UTC 15 September 2014.

638

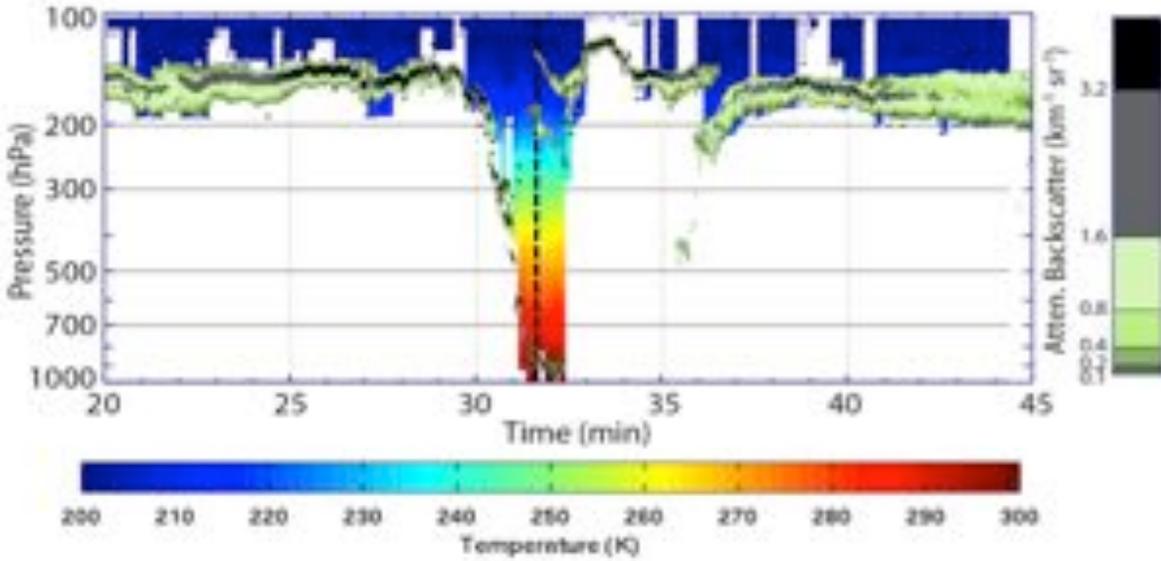

639

640 Figure 5. (a) S-HIS brightness temperatures (color shading, K) for the 895-900 cm⁻¹ channel. The
 641 eye of Edouard is labeled “Eye” near the warm brightness temperatures associated with the low
 642 clouds in the eye. The black dashed line shows the approximate flight path (line segments
 643 through dropsonde points only). Short curved line segments indicate dropsonde horizontal
 644 trajectories, with the release point coinciding with the flight path. Dropsonde times (UTC) are
 645 indicated. (b) Tangential velocity, (c) radial velocity, and (d) relative humidity with respect to
 646 water for temperatures $\geq 273.15\text{K}$ and with respect to ice at colder temperatures (color shading)
 647 derived from dropsonde data between 1935-2207 UTC 14 September. Dropsonde locations are

648 indicated by vertical lines. Grey shading in right panels shows CPL attenuated backscatter (ABS,
649 $\text{km}^{-1} \text{sr}^{-1}$) multiplied by 100. Vertical arrow in (b) indicates the location of the center dropsonde
650 at 2104 UTC.

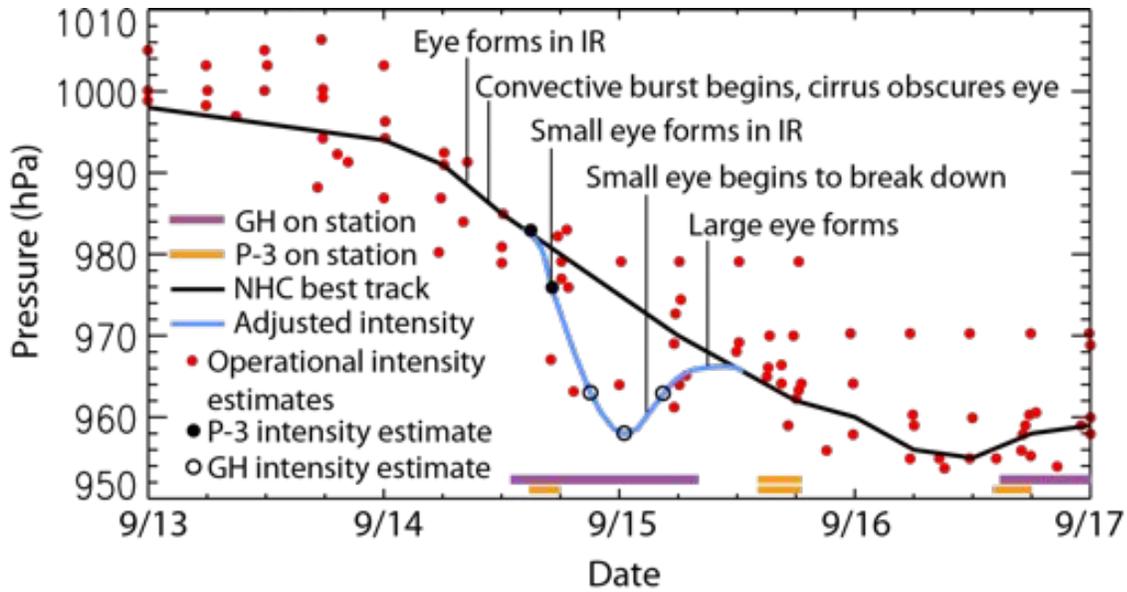

651

652

653 Figure 6. CPL attenuated backscatter ($\times 100$) and S-HIS real-time retrieved air temperature for
 654 the period 0020-0045 UTC 15 September during a transit over the storm from northeast to
 655 southwest of the center. Vertical dashed line shows the location of the 0032 UTC 15 September
 656 dropsonde.

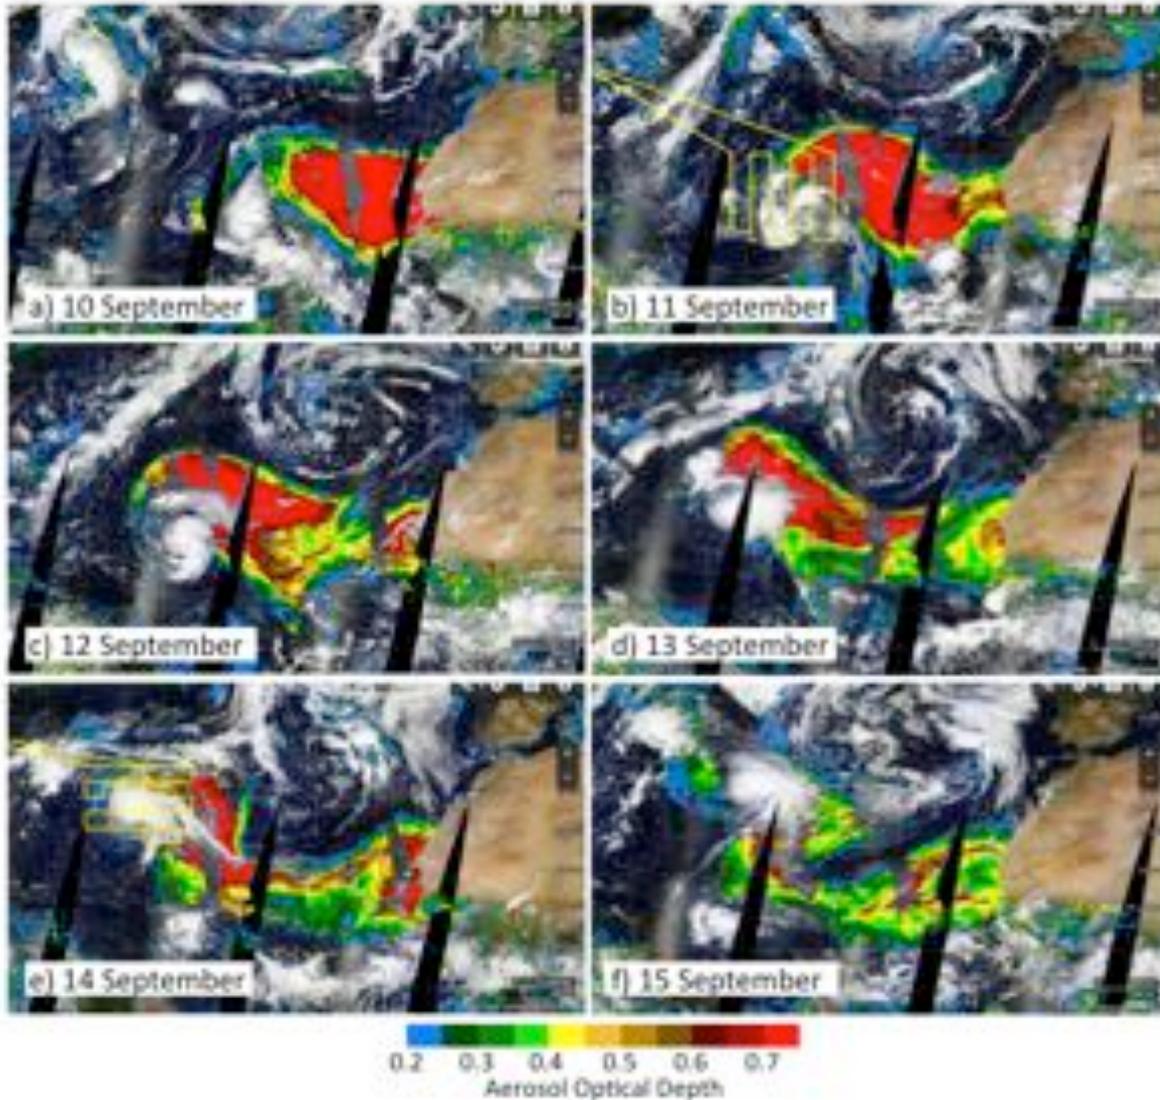

657

658

659 Figure 7. Time series of NHC best-track (black line) central pressure and operational intensity
 660 estimates (red circles, from satellite and aircraft). The blue line indicates estimated central
 661 pressures from P-3 (black circles) and GH (open circles) dropsondes. Orange and purple lines
 662 along the bottom of the figure indicate on-station times for NOAA P-3s and GH, respectively.
 663 Text indicates significant events during storm evolution.

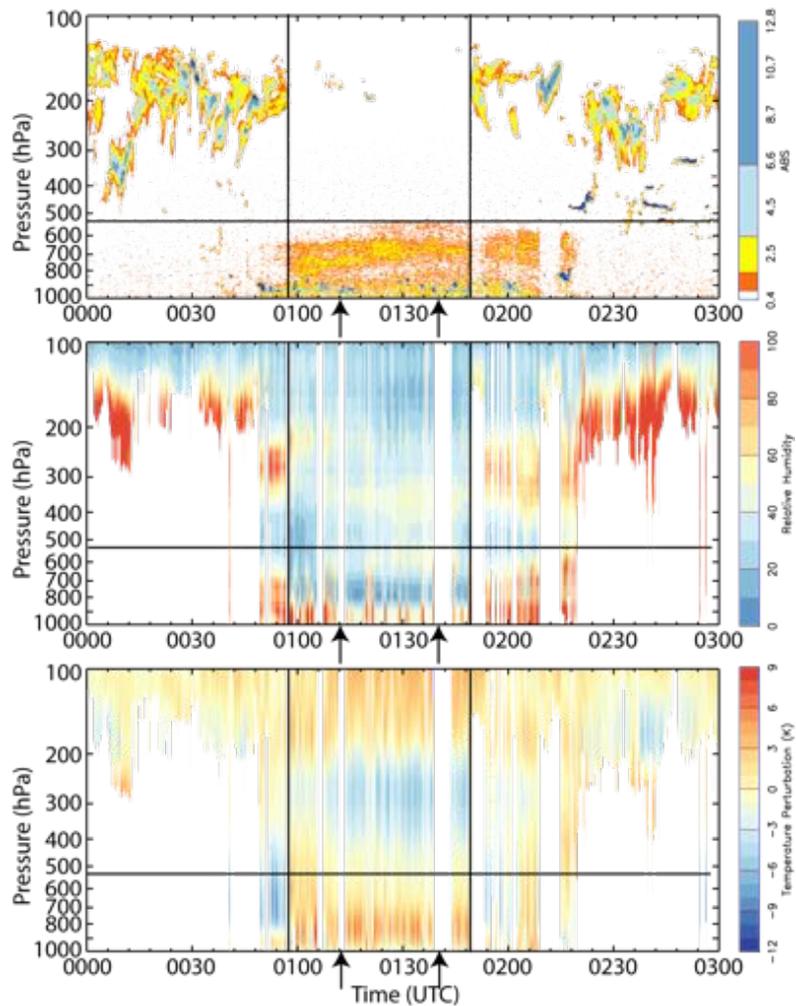

664

665

666 Figure 8. MODIS daily cloud and aerosol optical depth (colors) images show the evolution of the
 667 SAL outbreak near Hurricane Nadine on the indicated days. The flight track for the 11-12
 668 September flight is shown in (b) and for the 14-15 September flight in (e). MODIS imagery
 669 obtained from the NASA Worldview web page (<https://earthdata.nasa.gov/labs/worldview/>).

670

671

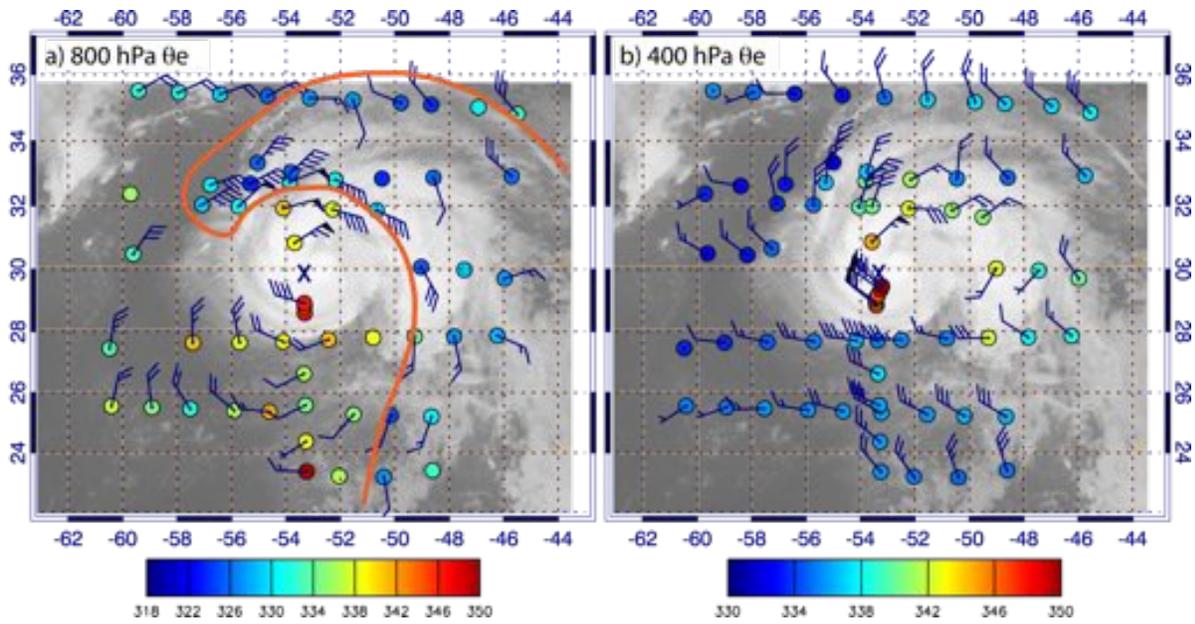

672 Figure 9. (a) CPL aerosol backscatter ($\times 100 \text{ km}^{-1} \text{ sr}^{-1}$) showing the dust layer north of Nadine
 673 along the northern portions of the 5th and 6th north-south oriented flight legs (from left to right in
 674 Fig. 8b) during the 11-12 September 2012 flight. S-HIS (b) relative humidity and (c) temperature
 675 perturbation for the same flight segment. Temperature perturbations are derived by removing the
 676 average temperature from 2000 UTC 11 September to 0600 UTC 12 September. The horizontal
 677 line marks the top of the dust layer, and the vertical lines separate times of nearly clear skies
 678 (0100-0149 UTC) from times with upper-level cloud cover. There is a reversal in the
 679 temperature anomalies below 400 hPa and much higher low-level relative humidity before 0100

680 UTC and after 0149 UTC, suggesting possible retrieval biases caused by upper-level clouds.

681 Vertical arrows indicate the times of aircraft turns, first from northbound to eastbound, second
682 from eastbound to southbound.

683

684

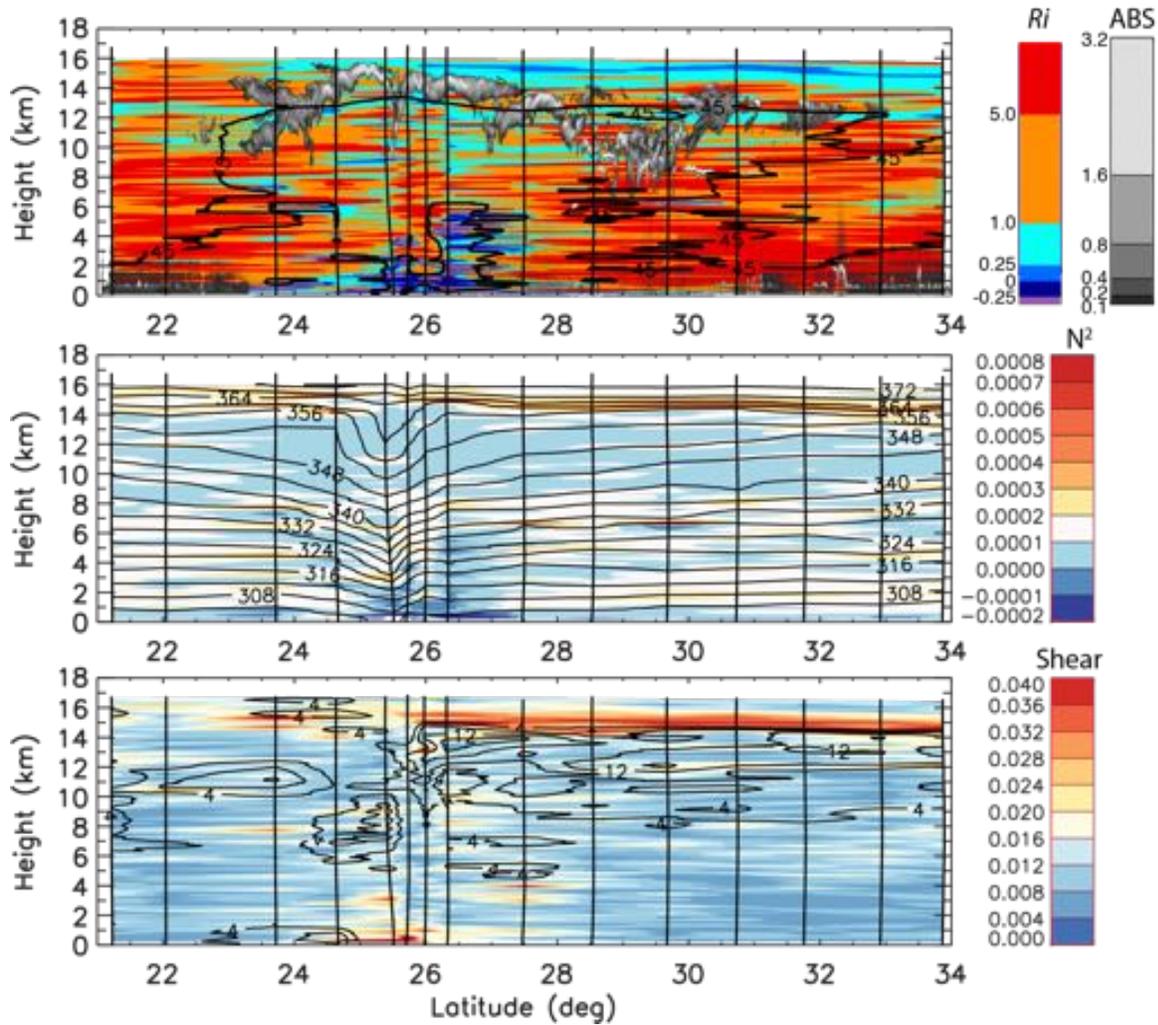

685

686 Figure 10. Equivalent potential temperature (colored circles) and storm-relative wind barbs (full
 687 barb, 5 m s^{-1} ; half-barb, 2.5 m s^{-1} ; flags, 25 m s^{-1}) at (a) 800 hPa and (b) 400 hPa superimposed on
 688 the GOES infrared imagery at 0015 UTC 15 September 2012. Dropsonde locations account for
 689 dropsonde drift and storm motion, with positions adjusted to a reference time of 0000 UTC 15
 690 September. Color bars indicate θ_e values (K) corresponding to the dropsonde data in each panel.

691

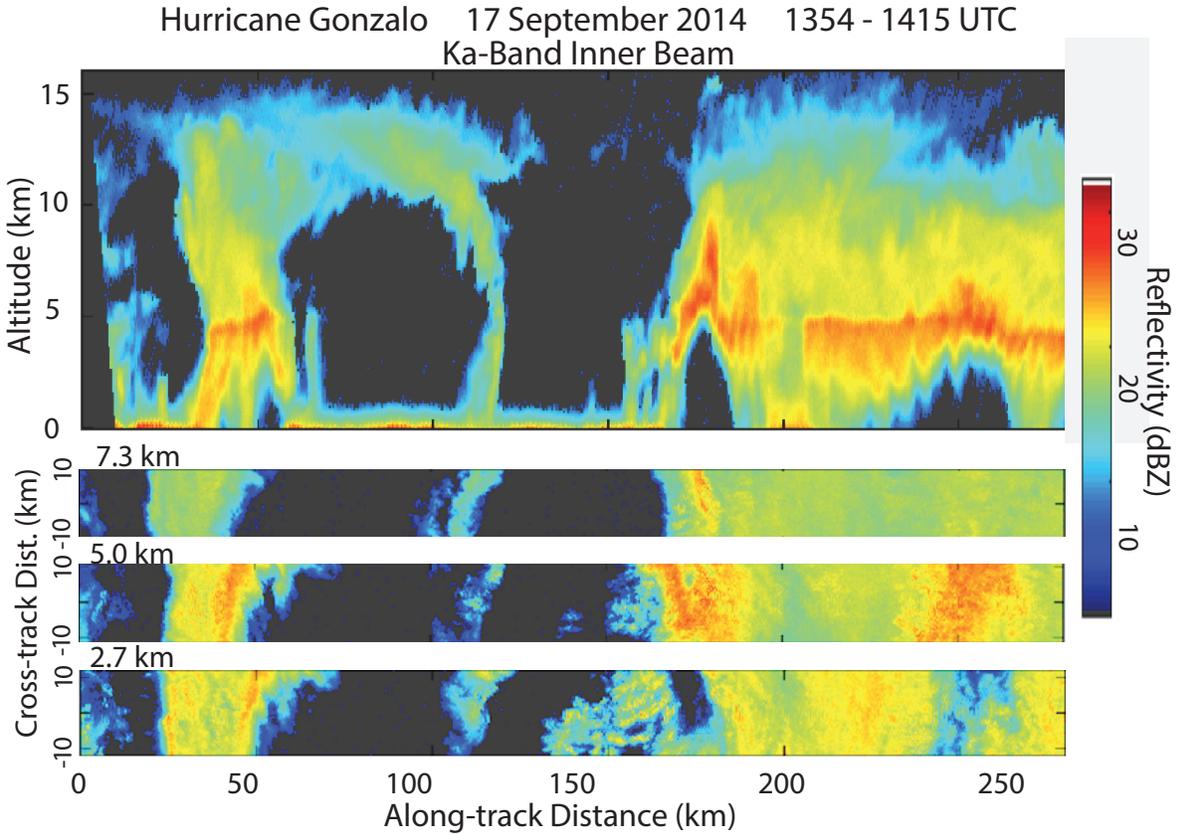

692

693

694 Figure 11. Plots of (a) bulk Richardson number and CPL attenuated backscatter ($\times 100 \text{ km}^{-1} \text{ sr}^{-1}$),
 695 (b) Brunt-Vaisala frequency, N^2 (s^{-2}), and (c) vertical wind shear, S (s^{-1}), for the Edouard cross
 696 section shown in Fig. 5. In (a), the 45% relative humidity contour is shown to indicate an
 697 approximate boundary of very dry air. In (b), contours are of potential temperature at 4 K
 698 intervals while in (c) contours show outflow regions with radial velocity at 4 m s^{-1} intervals
 699 starting at 4 m s^{-1} .

700

701

702 Figure S1. Hurricane Gonzalo on 17 September 2014 as observed from the HIWRAP Ka-band
 703 frequency as the storm was approaching Bermuda. Vertical cross section (top) and horizontal
 704 cross sections at 2.7, 5.0 and 7.3 km altitude (bottom panels) reconstructed from HIWRAP
 705 conical scanning outer beam. Both inner and outer eyewalls are observed at 110 and 160 km, and
 706 40 and 250 km, respectively. The Ka-band data shown has higher resolution than the Ku-band
 707 and is more sensitive to light precipitation at upper levels in the eyewall, but suffers more
 708 attenuation in heavy rain near the surface.
